Satellite NO₂ Trends: The Global View 1995-

GOME annual changes in tropospheric NO₂

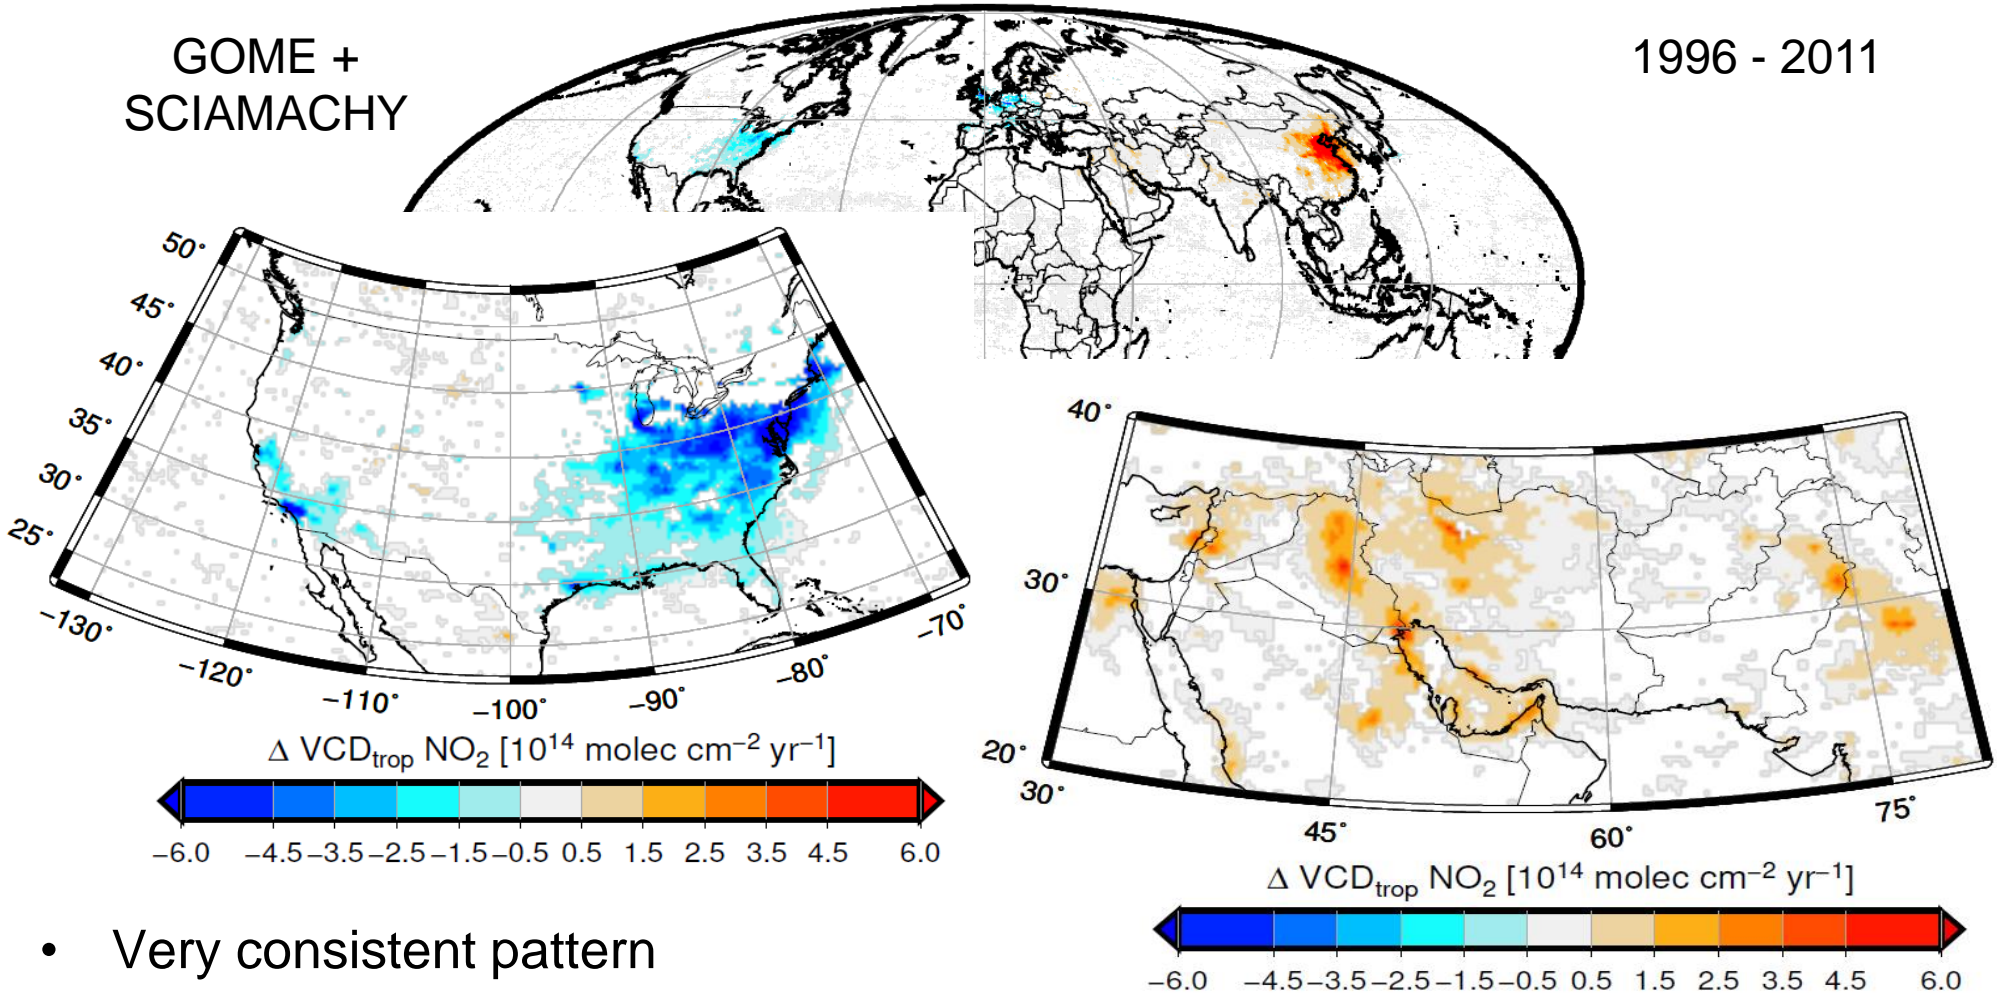

A. Richter et al., Increase in tropospheric nitrogen dioxide over China observed from space, *Nature*, 437 2005

The spatial distribution of satellite NO₂ trends

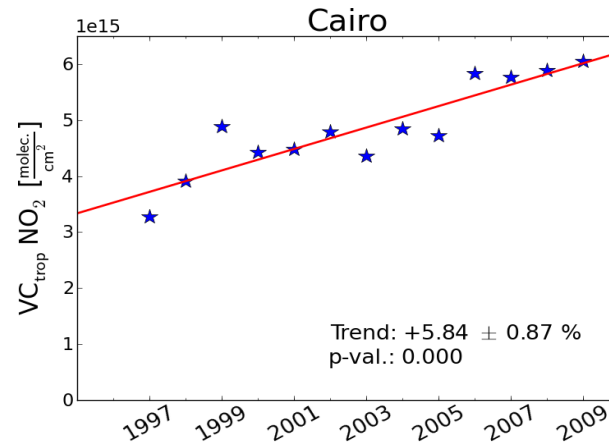

GOME +
SCIAMACHY

1996 - 2011

- Very consistent pattern
- Many cities can be identified

NO₂ Trends over some Megacities/Urban Agglomerations

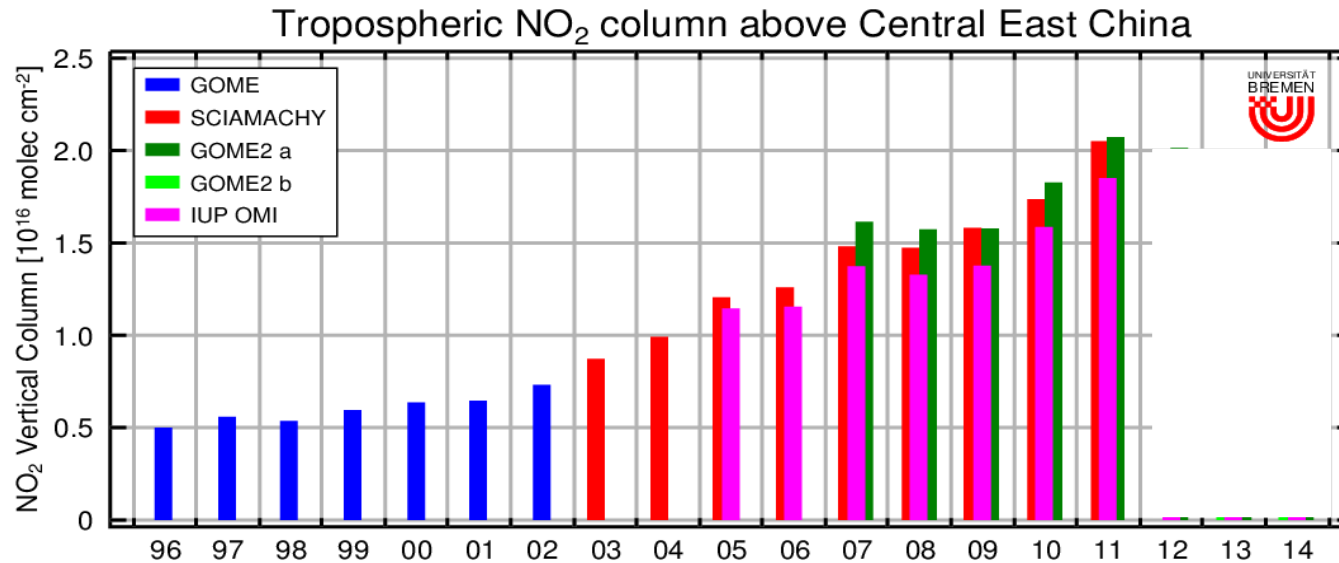

NO₂ levels are changing in cities throughout the world.

Contributing factors are

- Urbanisation
- Population growth
- Increase in standard of living
- changes in fuels used
- Improvements in emission controls

Recent NO₂ Trends above China

- Until 2011, there was continuous increase in NO₂
- After two years of stagnation, 2014 saw a large decrease
- ⇒ economic slow down?
- ⇒ Improved technology?
- ⇒ Switch in fuels used?
- ⇒ Other factors?

NO_x Emissions from Shipping

GOME-2 shipping NO₂ January 2007 - October 2010

Ship emissions:

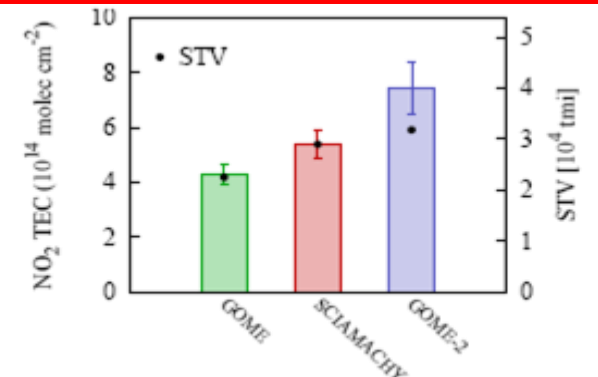

- large source of NO_x, SO_x and aerosols
- relevant input into marine boundary layer
- well defined NO₂ patterns in Red Sea and Indian Ocean in GOME-2 data
- consistent with pattern of shipping

With estimate of NO₂ lifetime, NO_x emissions can be estimated => agreement within error bars.

But: error bars mainly from lifetime)

10¹⁶ molec cm⁻²

MAX-DOAS Measurements in Athens

- Oct 2012 – now
- 330 – 500 nm
- 8 viewing azimuths
 - Ocean
 - Airport
 - City x 5
 - Background
- $-1^{\circ} \dots 30^{\circ}$ elevation + zenith
- 15 minutes cycle
- Closest zenith reference

- 3.2 million inhabitants
- Emissions from industry and transportation
- Intense photochemistry
- Affected by fires and Sahara dust events

Spatial Gradients City Pollution

All directions lowest values

Maximum city

Maximum clean regions

Biogenic Background direction largest

Residential area direction highest

Weekly Cycle in NO₂ for Athens

NO₂ weekly cycle Athens 2° view July 2013

NO₂ weekly cycle Athens 15° view July 2013

NO₂ weekly cycle Athens 30° view July 2013

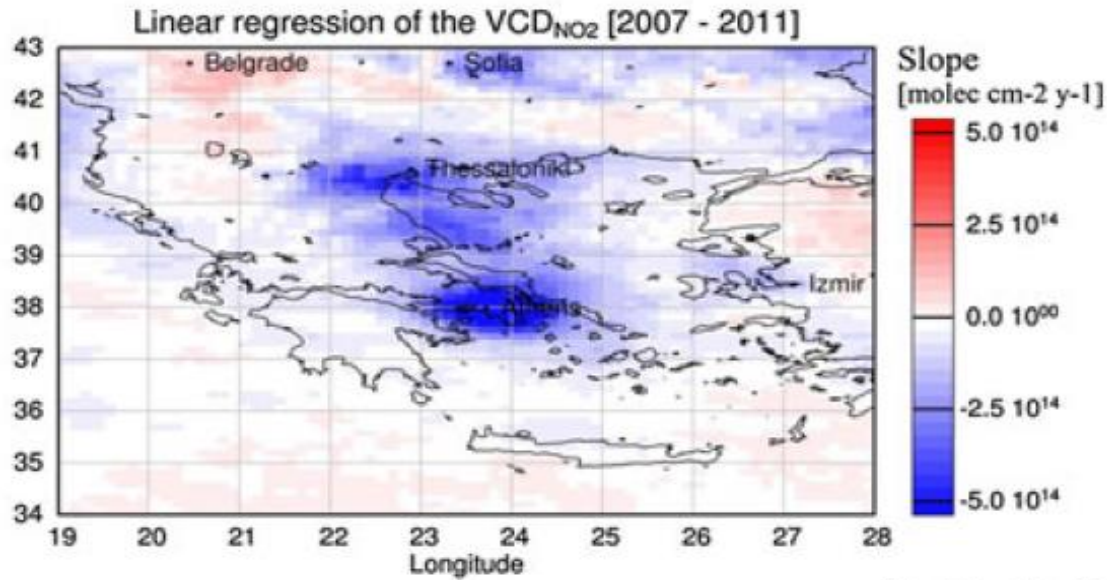

NO₂ weekly cycle Athens 2° view 2013

- Very clear weekly cycle
- Most pronounced over city directions
- Most pronounced in lowest elevation angles
- Best seen during summer break

NO₂ Trends above Europe

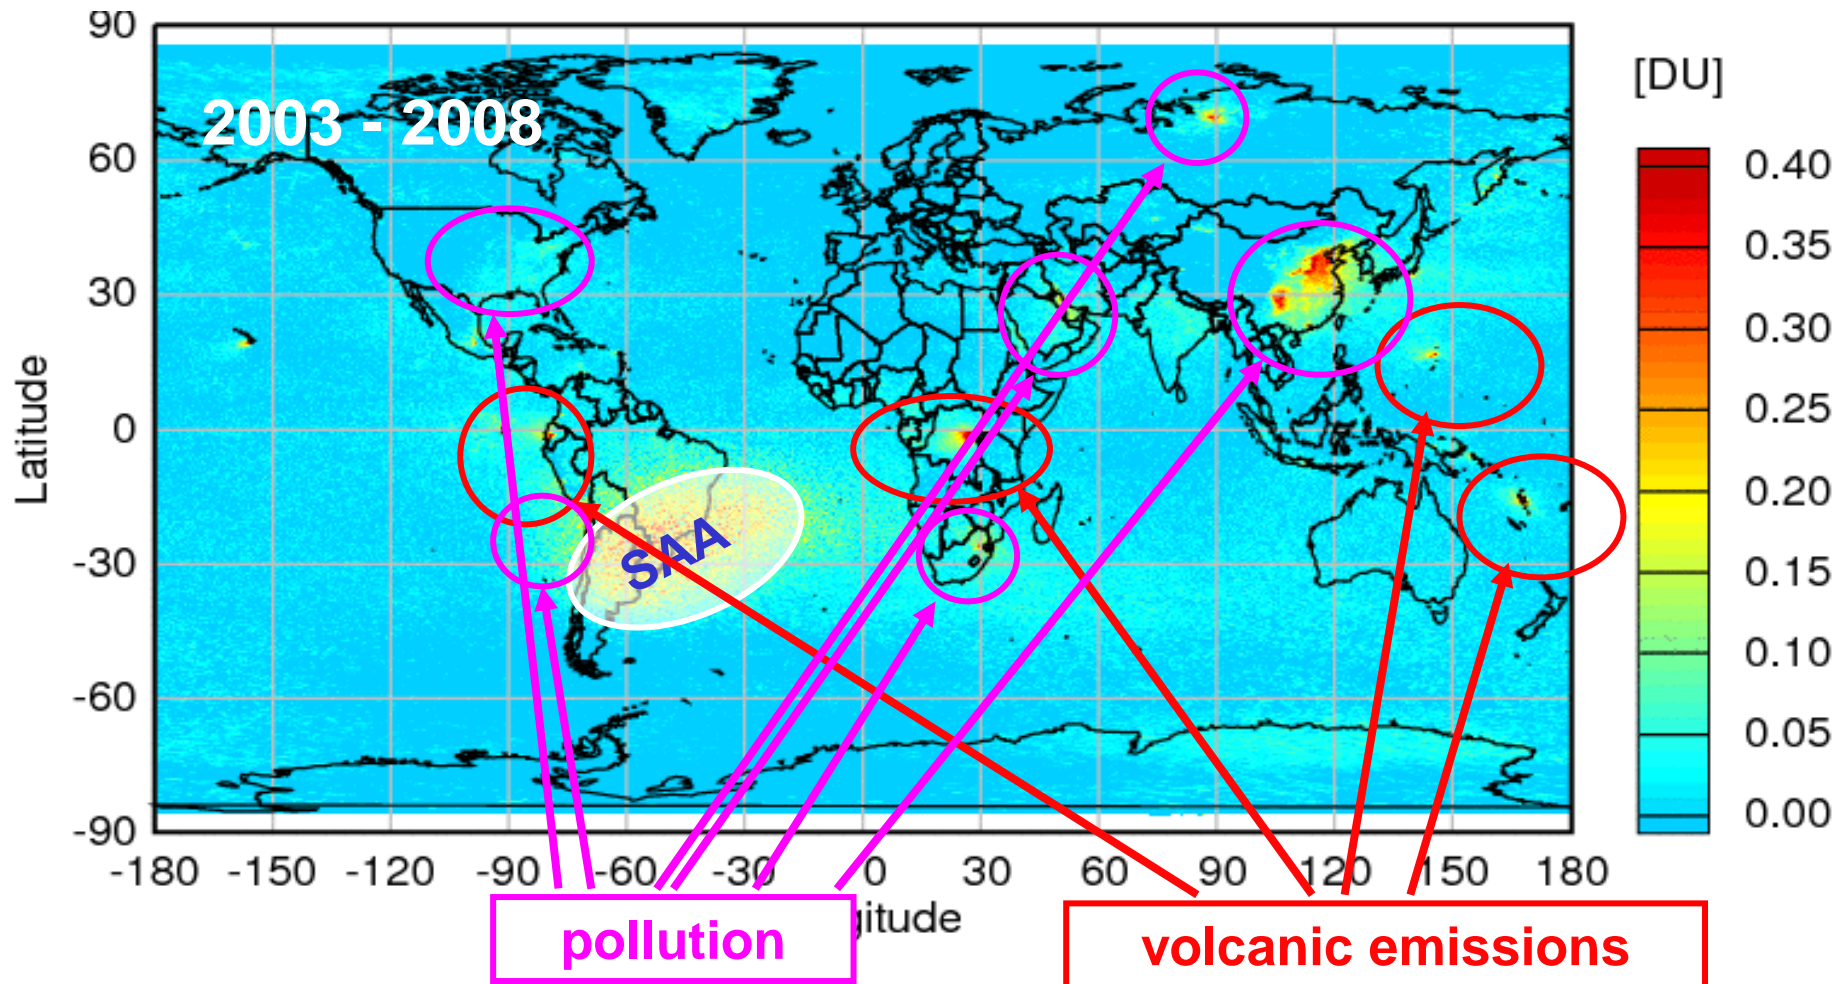

- Decreasing NO₂ trend over Greek cities from 2007 – 2011
- Both in satellite and surface data
- Link to oil consumption
- Effect of economic crisis

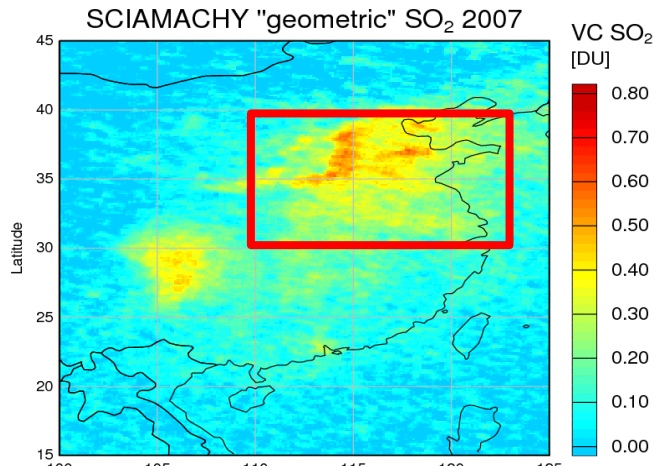

Vrekoussis, M. et al., Economic crisis detected from space: Air quality observations over Athens/Greece, Geophys. Res. Lett., 40, doi:10.1002/grl.50118., 2013

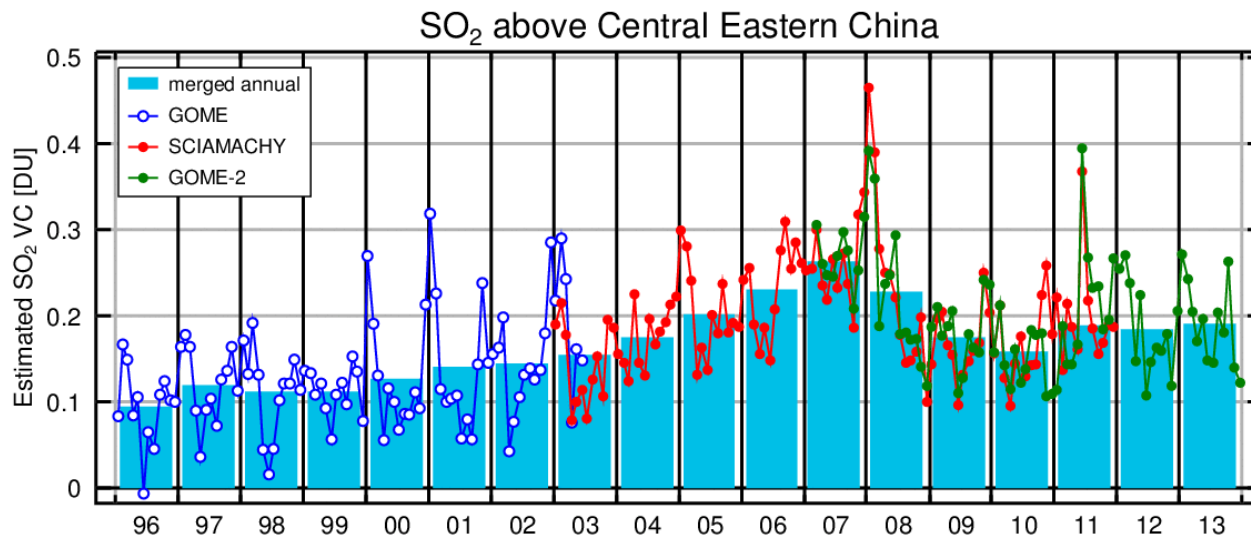

SCIAMACHY SO₂: The global Picture

SO₂ columns above China

- SO₂ increase in similar regions as NO₂ increase
- Main reason is increase in power generation using coal

- Legislation made flue gas desulphurisation mandatory after 2006
- Marked decrease in SO₂ but small upward trend since 2009 (industrial sources)

NMVOCs: HCHO and glyoxal

Sources:

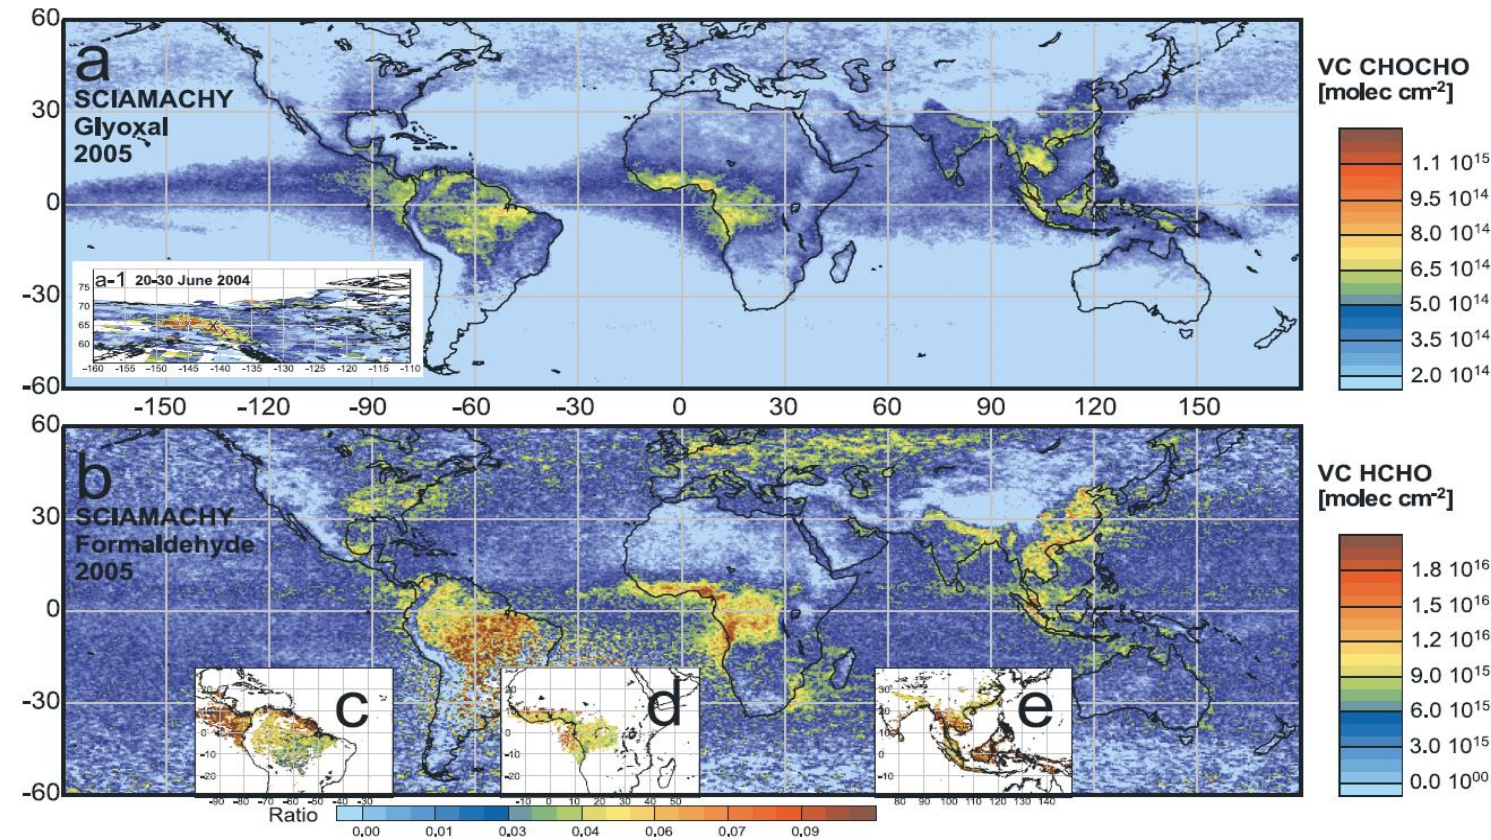

- Biogenic
- Fires
- Fossil fuel
- VOC oxidation

Sinks:

- Photolysis
- OH

Relevance:

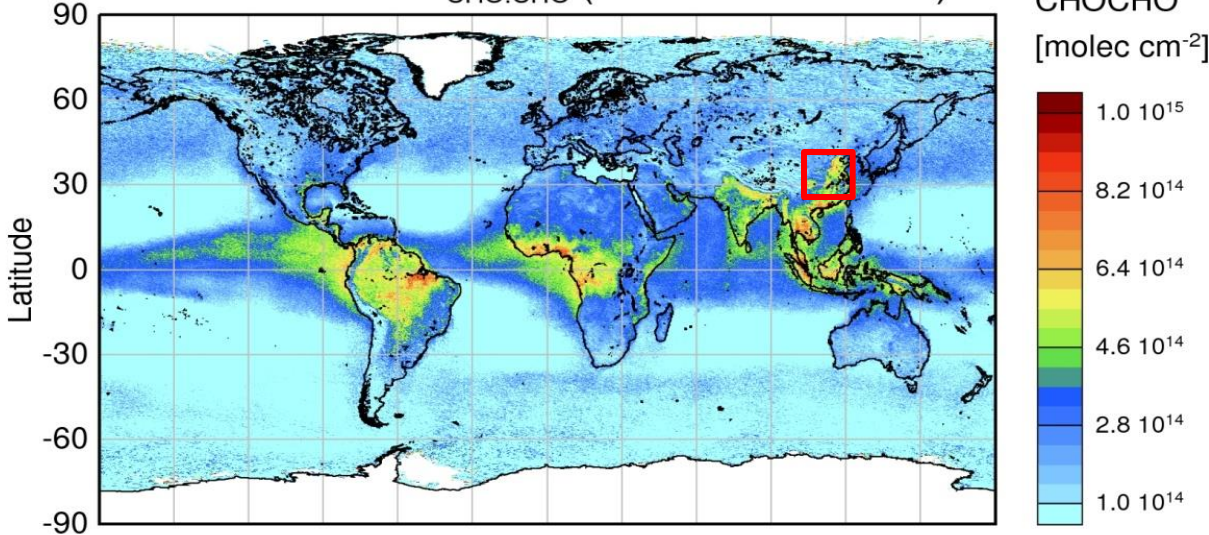

- O₃ production
- SOA

Wittrock, F., et al., (2006), Simultaneous global observations of glyoxal and formaldehyde from space, *Geophys. Res. Lett.*, 33, L16804, doi:10.1029/2006GL026310.

Glyoxal, CHO.CHO columns

SCIAMACHY VC_{CHO.CHO} (01.01.03 - 31.12.07)

- Glyoxal is a VOC with little primary emission
- Main sources are oxidation of biogenic and anthropogenic VOCs, biomass burning
- Seasonality of glyoxal indicates mainly biogenic precursors
- Consistent upward trend over SCIAMACHY time series
- Additional anthropogenic emissions?
- Land use changes?
- More biomass burning?

Asia (northern China)

CHOCHO NDVI fire counts

Highlight GHG

China

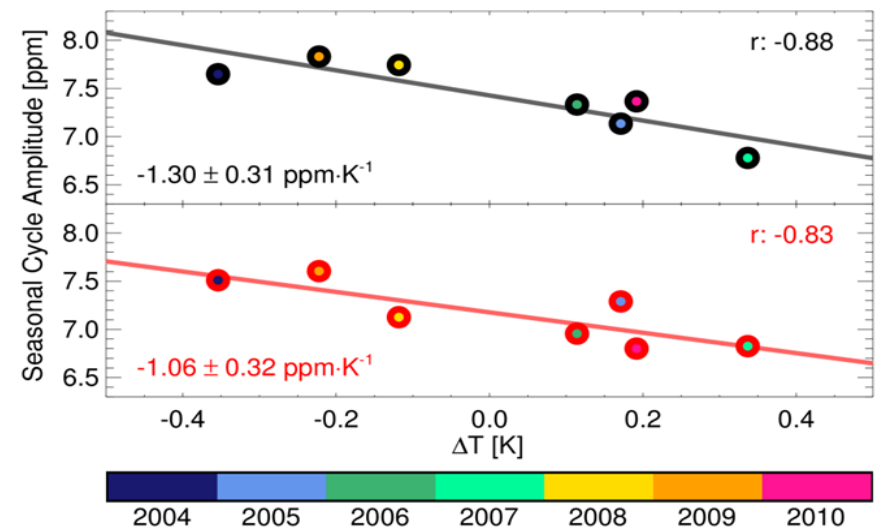

Temperature response of terrestrial carbon sink

(Schneising et al., 2014, ACP)

- Years with **higher surface temperatures** during the growing season are associated with **larger CO₂ growth rates** and **smaller seasonal cycle amplitudes** (reduced net carbon uptake by vegetation)
- **Temperature sensitivity:** 2.7 ± 0.7 GtC/yr/K
- **Positive carbon-climate feedback** unless the biosphere adapts its carbon storage under warming conditions in the longer term

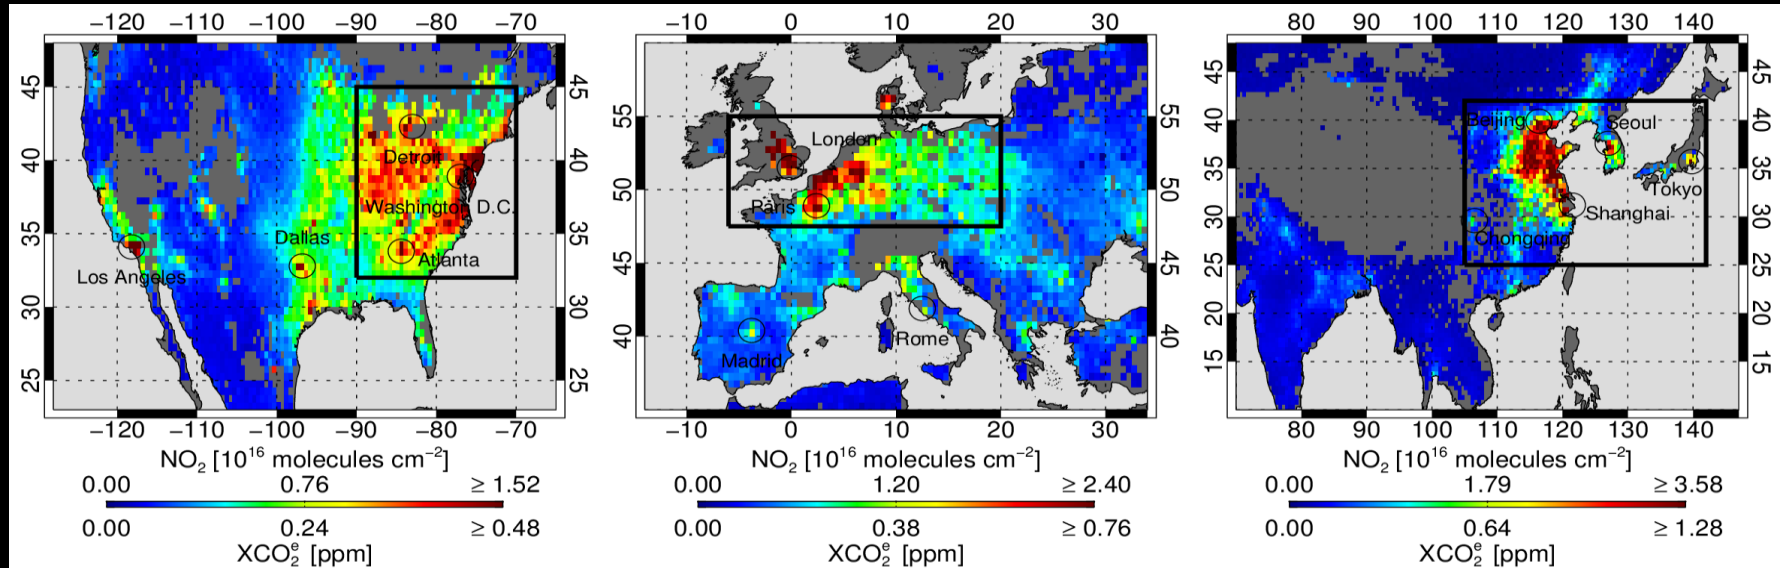

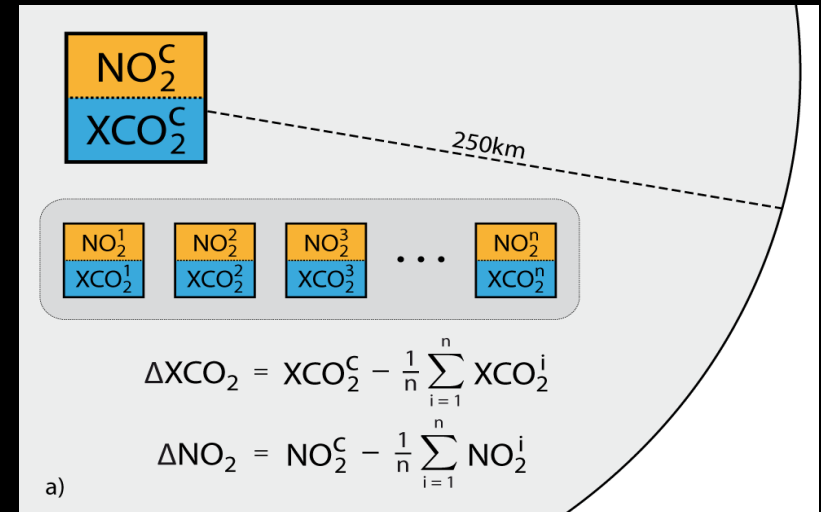

European Carbon Dioxide Surface Flux estimated from SCIAMACHY (and some GOSAT data)

European carbon uptake in gigatonnes of carbon in 2010

Anthropogenic CO₂ and NO_x emissions (Reuter et al., 2014, nat. geosci.)

- CO₂ and NO_x are **co-emitted** species in anthropogenic fossil fuel combustion processes.
- A **spatial high-pass filtering** method is used to derive co-located regional anomalies ΔXCO₂ and ΔNO₂.
- A **statistical relationship** between ΔXCO₂ and ΔNO₂ allows to conclude on **CO₂ with anthropogenic origin**.

Anthropogenic CO₂ and NO_x emissions (Reuter et al., 2014, nat. geosci.)

- We find significantly **lower ΔXCO₂ levels at weekends** in North America and Europe but not in East Asia.
- The weekend effect of XCO₂ is a tiny signal and this is its **first detection from space**.
- It underlines that the analyzed CO₂ signals originate from **anthropogenic activities**.

Anthropogenic CO₂ and NO_x emissions (Reuter et al., 2014, nat. geosci.)

- **North America and Europe:** satellite data show a small **downward trend in emissions** of both, NO_x and CO₂ albeit associated with a large uncertainty.
- **East Asia:** CO₂ emissions increased on average at a rate of 9.8%/a but NO_x increased “only” by 5.8%/a, i.e., significantly less compared to CO₂ (**increasing CO₂-to-NO_x emission ratio F**).
- **Interpretation: technology** used in East Asia is **getting cleaner** thus emitting less toxic nitrogen gases per amount of fossil fuel burned.

Methane

- Second most important anthropogenic GHG (directly after CO₂)
- Important precursor of O₃ in global tropospheric Chemistry
- Many anthropogenic and natural sources; large uncertainties

Natural Methane Sources (2000s)

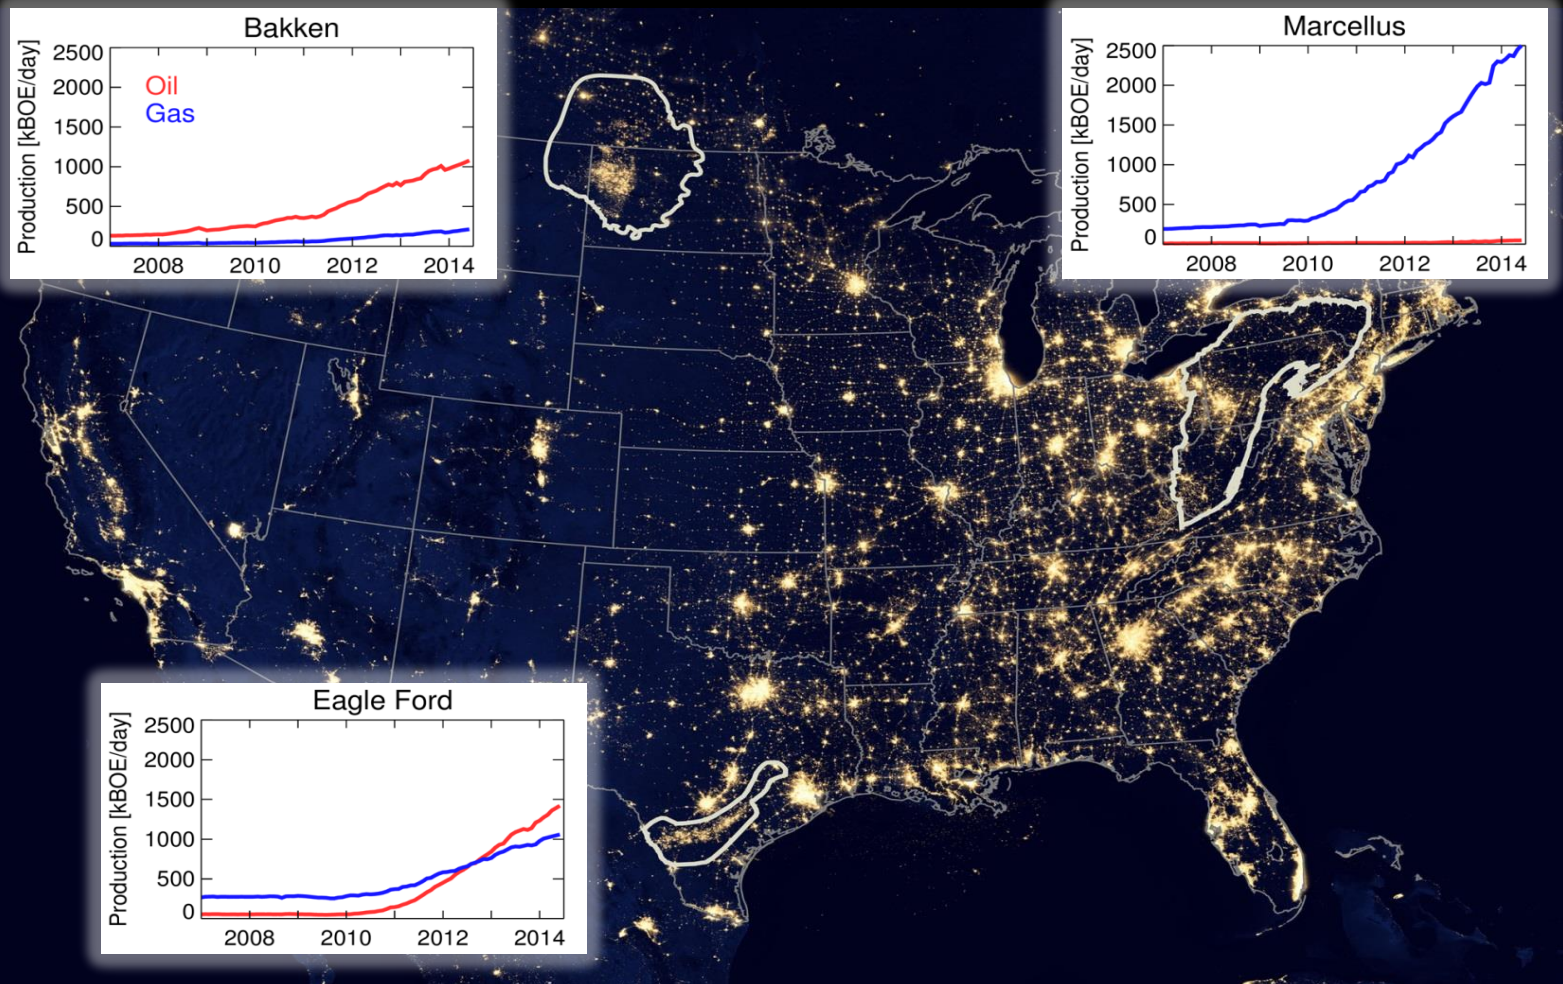

Anthropogenic Methane Sources (2000s)

Kirschke et al.,

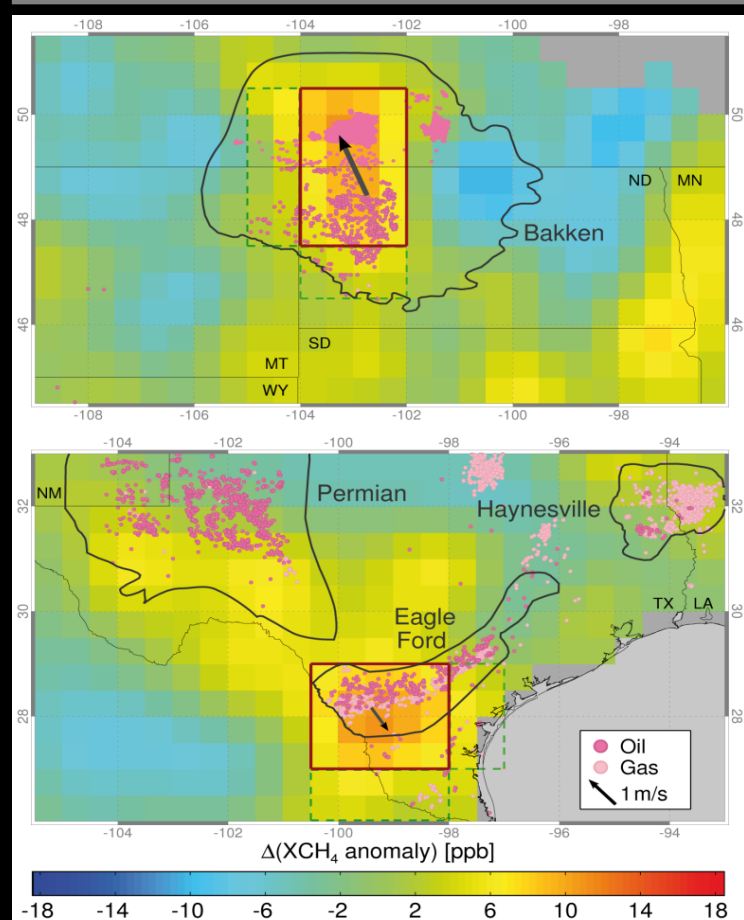

Fugitive methane emissions from oil and gas production (Schneising et al., 2014, Earth's Future)

- We analyse **methane enhancements** over the fastest growing production regions in the U.S.
- Flaring in **Bakken** and **Eagle Ford** is so extensive that both regions stand out clearly in satellite measurements of nighttime lights from VIIRS onboard Suomi NPP.

Fugitive methane emissions from oil and gas production (Schneising et al., 2014, Earth's Future)

- To filter out large-scale seasonal variations or global increase, **XCH₄ anomalies** are computed by subtracting regional monthly means from the individual measurements.
- The shown **differences of the anomalies** for the period **2009-2011** relative to the period **2006-2008** highlight the changes in atmospheric methane abundance.
- Anomaly differences exhibit **increases aligning with the analysed oil and gas fields.**

Fugitive methane emissions from oil and gas production (Schneising et al., 2014, Earth's Future)

Bakken

Emission Increase:

990 ± 650 ktCH₄/yr

Leakage rate:

10.1 ± 7.3 %

Eagle Ford

Emission Increase:

530 ± 330 ktCH₄/yr

Leakage rate:

9.1 ± 6.2 %

- The **emission increase** is quantified by a mass-balance approach using the net enhancement relative to the background upwind of the prevailing wind direction and average horizontal boundary layer wind speed.
- The **leakage rate** is defined as the ratio of the emission increase between 2006-2008 and 2009-2011 divided by the production growth between these two periods.
- **Results:** Current inventories likely underestimate fugitive emissions from Bakken and Eagle Ford. Climate benefit of transition to unconventional oil and gas is questionable.

CarbonSat: Methane @ high latitudes
