Outline

1. Ocean colour historical background

2. Radiative transfer – Modelling

3. Ocean colour remote sensing
   Basic principles
   Sensors
   Calibration and validation

4. Marine optics & Biogeochemistry
   - Case 1 & Case 2 waters
   - Apparent & inherent optical properties

5. Introducing ocean colour algorithms and products
   - Atmospheric corrections
   - Inversion algorithms
   - Processing software and ocean colour products

6. Applications

**7. References**

1. Ocean colour historical background

Poseidon's paintbox: Historical archives of ocean colour in global change perspective, by Dr. Marcel R. Wernand, ISBN: 97890-6464-509-9.

• Describes the gradual understanding of the transparency (clarity) and degrees of coloration of natural waters from H. Hudson (~1600) to C. Raman (1970),

• Highlights reports of explorers and scientists (how is it related to water quality and contents?),

• Explains the development of instruments (Secchi disc, Forel-Ule scale, etc.)

• Relates Raman (1922) discoveries on light (blue) scattering and absorption (long visible wavelengths) by water molecules.

Physical measurement of the « ocean colour » =

Radiance L in W/m²/sr/nm, i.e. the light intensity coming from a specific direction
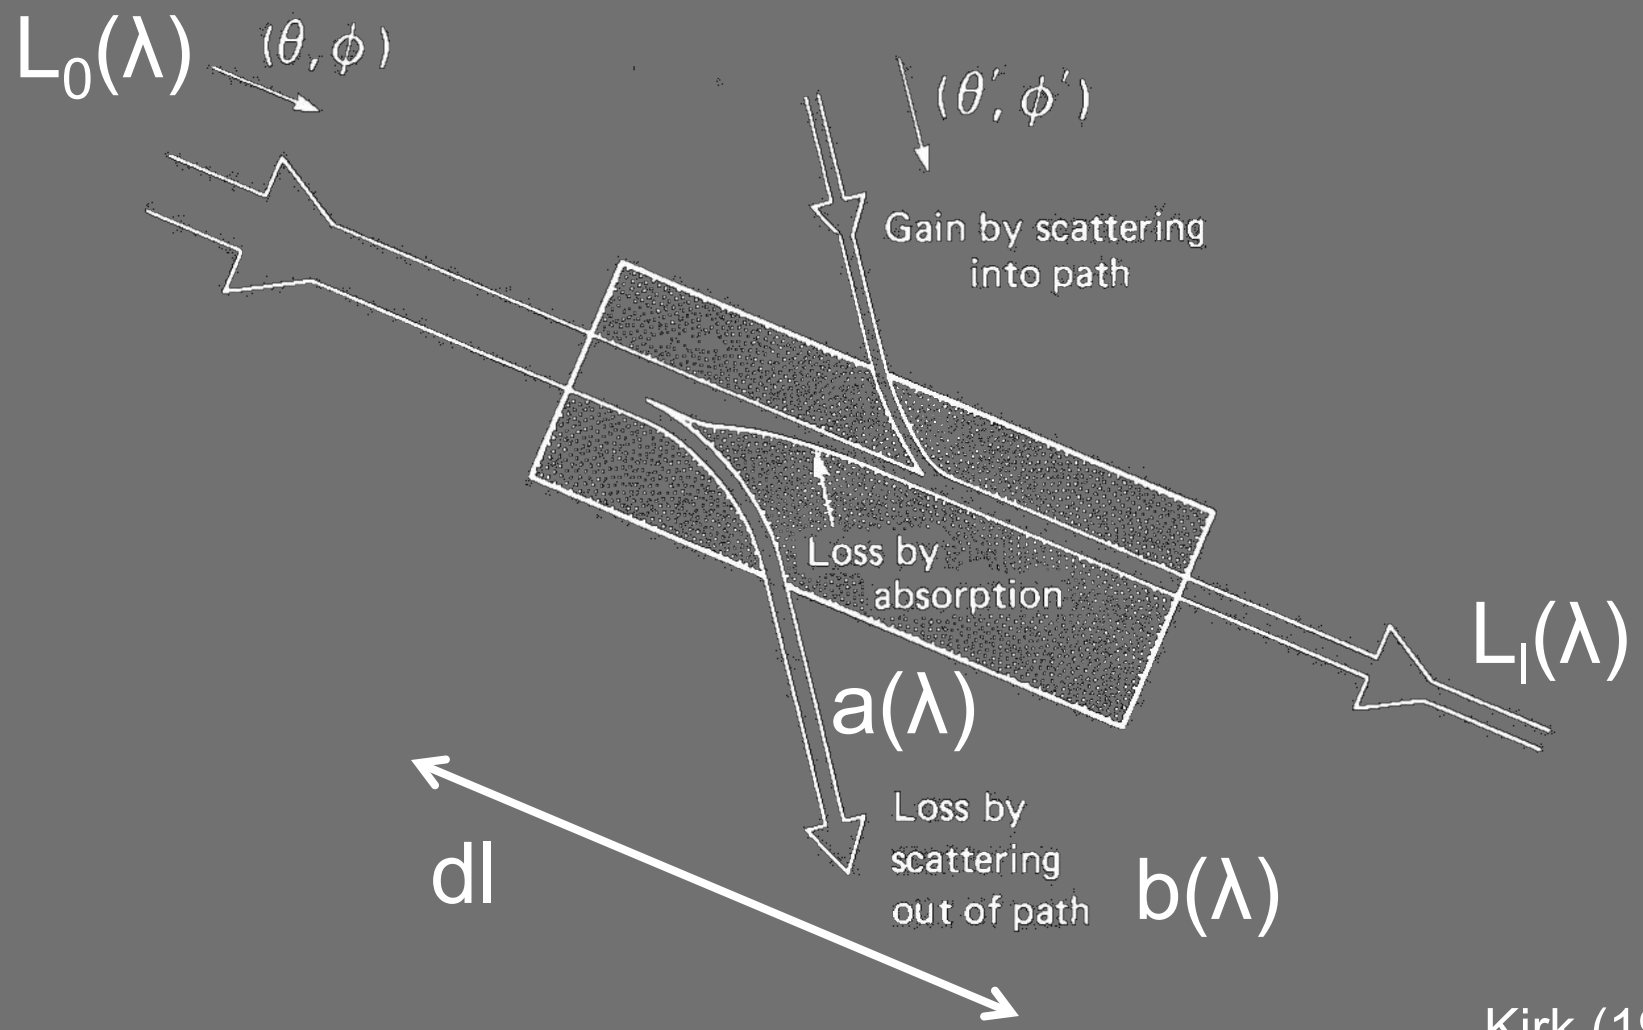

➔ $R_{rs} = L_w / E_d$, en 1/sr

Derived from ocean colour satellite data

2. Radiative transfer – Modelling

Radiative transfer is the physical phenomenon of energy[*] transfer in the form of electromagnetic radiation. The propagation of radiation through a medium (atmosphere, natural waters and interfaces) is affected by absorption, emission, and scattering processes. The radiative transfer equation describes these interactions mathematically.

Radiative transfer numerical models compute radiance distributions and derived quantities (irradiances, reflectances, K functions, etc.) within the atmosphere and natural water bodies.

[*] Here radiance (in $W.m^{-2}.sr^{-1}.nm^{-1}$), i.e. number of photons at specific wavelength and direction and per unit of solid angle.

Loss by absorption

$L_l(\lambda)$

$a(\lambda)$

Loss by scattering out of path

dl

$b(\lambda)$
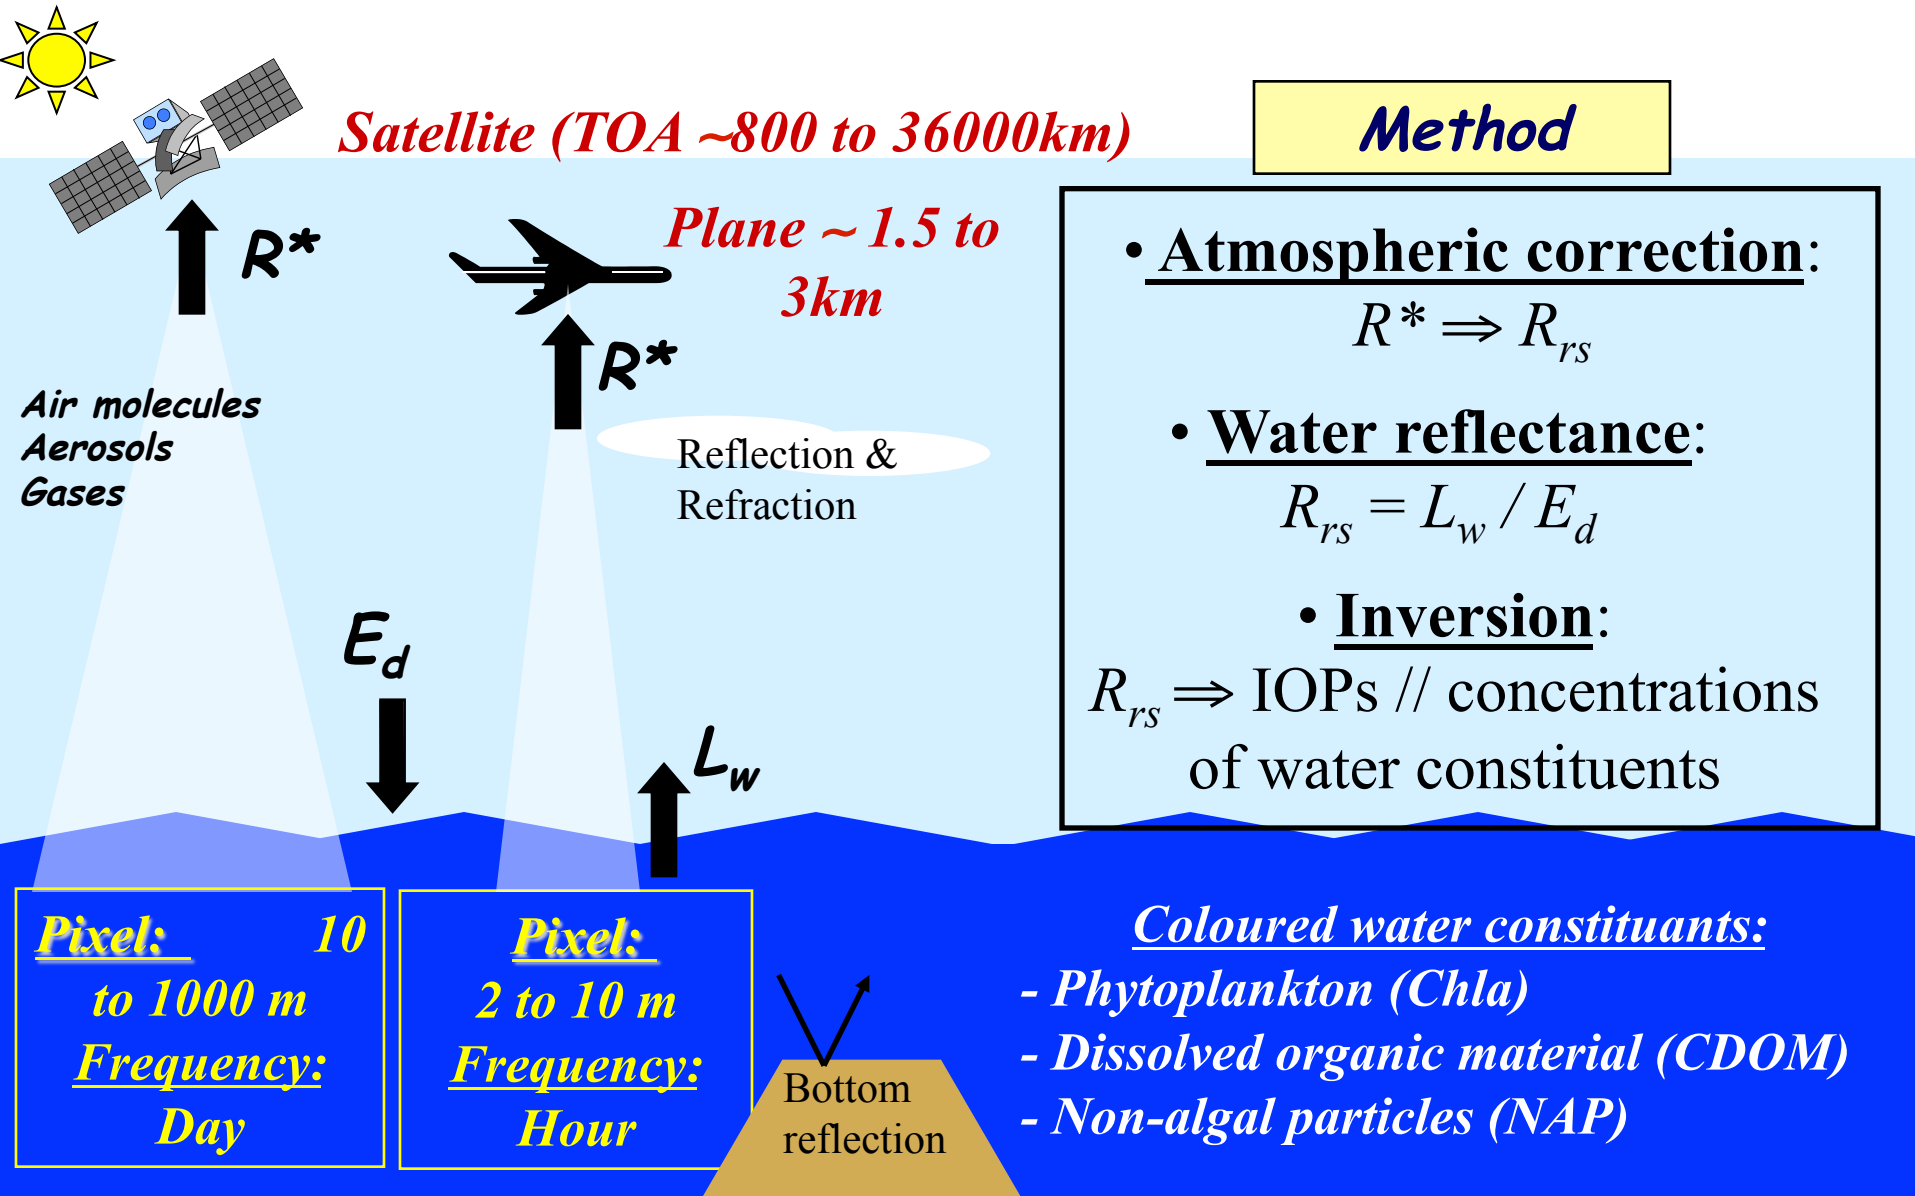

Kirk (1983)

Examples of codes:

HydroLight (Mobley 1994) solves the 1D time-independent radiative transfer equation to compute the radiance distribution within and leaving any plane-parallel water body. The spectral radiance distribution is computed as a function of depth, direction, and wavelength within the water.

6S (Vermote et al. 1997)) and **MODTRAN** (Acharya et al. 1999) codes solve the radiative transfer equation including the effects of molecular and particulate absorption/emission and scattering, surface reflections and emission, solar/lunar illumination, and spherical refraction.

Also:

Monte Carlo simulations have been widely used to solve and understand marine optics and ocean colour remote sensing problems (e.g., Kirk 1992, 1993).

Mie theory allows computing the absorption, scattering and attenuation of light by particles of different composition, size and shape (Bohren and Huffmann 1983).

Vicarious calibration / Validation

MERIS matchups (in terms of rw) at the BOUSSOLE site, including the following wavelengths : 412, 443, 490, 510, 560, 670, 683 nm. The same data are plotted with a linear scale on the left and a log scale on the right, in order to highlight the low reflectance values of the red wavelengths. The solid line is the 1:1 line. The dotted line is a simple linear fit on the data. The slope and intercept of this curve are also indicated.
Classification of natural waters

Figure 1. Partitioning of seawater into optical main optical classes.

• **Phytoplankton chlorophyll (and degraded products) is the unique coloured constituent in Case 1 waters**

• **Case 2 waters are also influenced by terrestrial substances (NAP, gelbstoff)**

Morel / Antoine MERIS Case 1 water ATBD

Apparent and inherent optical properties

Preisendorfer (1961): apparent optical properties (**AOPs**) depend on the **radiance distribution** whereas inherent optical properties (**IOPs**) such as the absorption coefficient (**a**), the scattering coefficient (**b**), and the beam attenuation coefficient (**c**) which are intrinsic properties of the aquatic medium itself not affected by the prevailing distribution of radiance.

AOPs (radiometric measurements)

R = Eu/Ed (dl); **Rrs** = Lw/Ed (1/sr) = reflectance or colour of the water

Ed(z) = Ed (0-) exp(-**Kd** × z) = Solar light penetration into water column

Apparent and inherent optical properties

Semi-analytical models relating the AOPs and IOPs (Gordon et al. 1975, Morel & Prieur 1977, Kirk 1983), e.g.:

$$K_d \cong (a + b_b) / \cos(\theta_{sw}) \qquad (1/m)$$

$$R \cong f \times b_b / (a + b_b)$$

Total absorption and backscattering coefficients (a and b_b, in 1/m) are the sums of contributions by pure water (w), phytoplankton (Chla), non-algal particles (NAP) and gelbstoff (y):

$$a = a_w + a_{Chla} + a_{NAP} + a_y$$

$$b_b = b_{bw} + b_{bChla} + b_{bNAP}$$

IOPs measurements

Light absorption (*a*) can be measured using:

• Collimated source, reflective sample cell with diffuser in front of wide area detector (Wetlabs ac9, acs)

• Spectrophotometers (cuvette, filter-pads)

Light backscattering (β) is measured at specific angles:

$$b = 2\pi \int_{0}^{\pi} \sin(\theta)\beta(\theta)d\theta \qquad b_b = 2\pi \int_{\frac{\pi}{2}}^{\pi} \sin(\theta)\beta(\theta)d\theta$$

total scatter   backscatter

θ = angle $\beta(\theta)$ = volume scattering function (m^{-1} sr^{-1})

Spectral absorption coefficients.

(SeaWiFs, MODIS)**
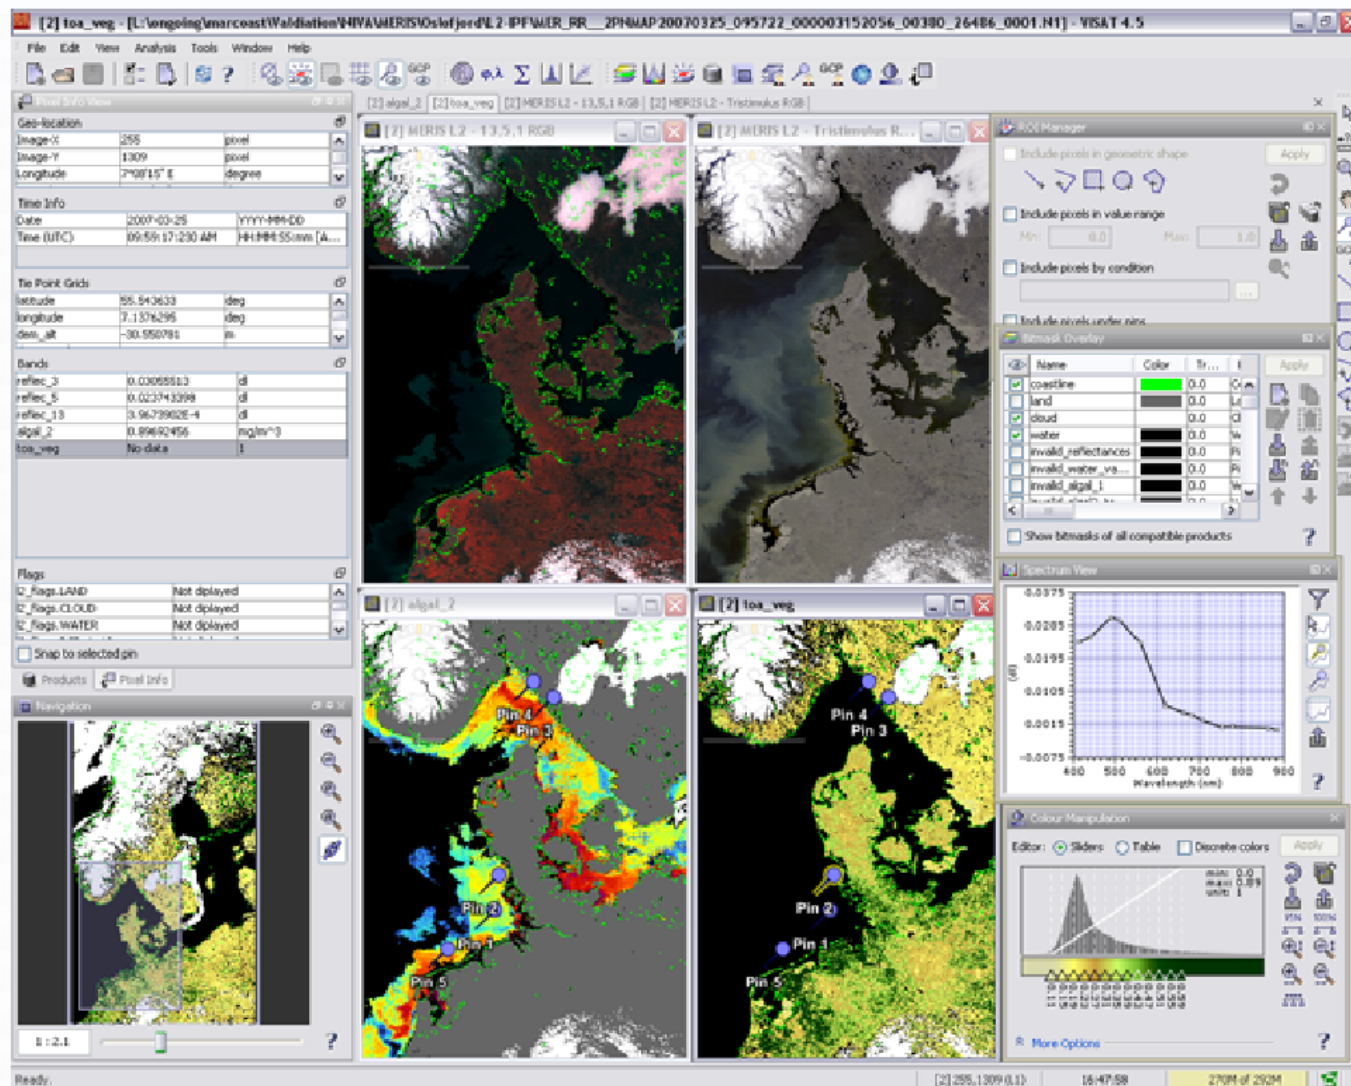

In Case-1 and Case-2waters, ocean colour remote sensing provides useful information on:

• Primary production

• Formation/degradation of particulate matter

• Organic carbon fluxes and cycles

• Food web / Ecosystems dynamics

• Fishery and (harmful) algal blooms

• Water quality

• Sediment transport and dynamics, fluxes

• etc…

Case-1 waters

Primary production of the global ocean
(Antoine et al. 1996)

Impact of Climate Change
(Martinez et al. 2009)

Figure 3. Annual primary production within the world ocean (equal surface "Mollweide" projection), obtained by summing the 12 monthly maps. This map shows the values obtained through the "standard" computation, which leads to a global annual carbon fixation of 36.5 Gt C yr⁻¹ (Table 1, line 1). This map can be compared to the historical primary production maps, as derived from compilations of in situ carbon fixation [e.g., *Koblentz-Mishke et al.*, 1970; *Berger et al.*, 1987].
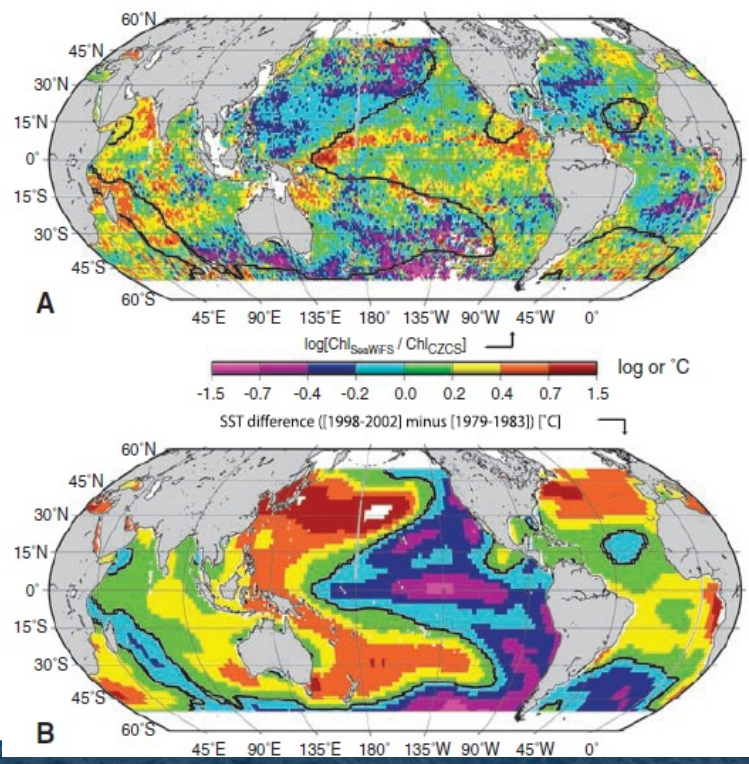

Case-2 waters

Detection of phytoplankton blooms
(Froidefond et al. 1999)
Fluxes at the land/ocean interface
(Doxaran et al. 2012)
